    Which of the following are true? (Check all that apply.)

     lacksquare a^{[2]} denotes the activation vector of the 2^{nd} layer.
     lacksquare X is a matrix in which each column is one training example.
     \square \ \ a_4^{[2]} is the activation output of the 2^{nd} layer for the 4^{th} training example
     lacksquare a^{[2](12)} denotes the activation vector of the 2^{nd} layer for the 12^{th} training example.
     lacksquare a_4^{[2]} is the activation output by the 4^{th} neuron of the 2^{nd} layer
2. The tanh activation usually works better than sigmoid activation function for hidden units because the mean
                                                                                                                          1 point
     of its output is closer to zero, and so it centers the data better for the next layer. True/False?
    True
     ○ False
3. Which of these is a correct vectorized implementation of forward propagation for layer l, where 1 \leq l \leq L?
                                                                                                                         1 point
    igcolum_{l} igcolum_{l} Z^{[l]} = W^{[l]} A^{[l]} + b^{[l]}
          ullet \ A^{[l+1]} = g^{[l]}(Z^{[l]})
    igcolum_{l} igcolum_{l} Z^{[l]} = W^{[l-1]} A^{[l]} + b^{[l-1]}
           ullet \ A^{[l]} = g^{[l]}(Z^{[l]})
     left \qquad left Z^{[l]} = W^{[l]} A^{[l-1]} + b^{[l]}
           ullet \ A^{[l]} = g^{[l]}(Z^{[l]})
    igcolum_{l} igcolum_{l} Z^{[l]} = W^{[l]} A^{[l]} + b^{[l]}
           ullet \ A^{[l+1]} = g^{[l+1]}(Z^{[l]})
4. You are building a binary classifier for recognizing cucumbers (y=1) vs. watermelons (y=0). Which one of these
                                                                                                                         1 point
     activation functions would you recommend using for the output layer?
     ○ ReLU
     Leaky ReLU
     sigmoid
     O tanh
                                                                                                                          1 point
5. Consider the following code:
        1 A = np.random.randn(4,3)
         B = np.sum(A, axis = 1, keepdims = True)
     What will be B.shape? (If you're not sure, feel free to run this in python to find out).
     (1, 3)
     (4, 1)
     (, 3)
     (4,)
 6. Suppose you have built a neural network. You decide to initialize the weights and biases to be zero. Which of
                                                                                                                          1 point
     the following statements is true?

    Each neuron in the first hidden layer will perform the same computation. So even after multiple

         iterations of gradient descent each neuron in the layer will be computing the same thing as other
         neurons.
      Each neuron in the first hidden layer will perform the same computation in the first iteration. But after
         one iteration of gradient descent they will learn to compute different things because we have "broken
        symmetry".
      Each neuron in the first hidden layer will compute the same thing, but neurons in different layers will
         compute different things, thus we have accomplished "symmetry breaking" as described in lecture.
     The first hidden layer's neurons will perform different computations from each other even in the first
         iteration; their parameters will thus keep evolving in their own way.
7. Logistic regression's weights w should be initialized randomly rather than to all zeros, because if you initialize
                                                                                                                          1 point
    to all zeros, then logistic regression will fail to learn a useful decision boundary because it will fail to "break
     symmetry", True/False?
     O True
     False
 8. You have built a network using the tanh activation for all the hidden units. You initialize the weights to relative
                                                                                                                         1 point
     large values, using np.random.randn(..,..)*1000. What will happen?
     This will cause the inputs of the tanh to also be very large, thus causing gradients to be close to zero.
         The optimization algorithm will thus become slow.
     This will cause the inputs of the tanh to also be very large, thus causing gradients to also become large.
         You therefore have to set lpha to be very small to prevent divergence; this will slow down learning.
      This will cause the inputs of the tanh to also be very large, causing the units to be "highly activated" and
         thus speed up learning compared to if the weights had to start from small values.
     O It doesn't matter. So long as you initialize the weights randomly gradient descent is not affected by
         whether the weights are large or small.
                                                                                                                          1 point
9. Consider the following 1 hidden layer neural network:
     Which of the following statements are True? (Check all that apply).
    lacksquare b^{[1]} will have shape (4, 1)
    lefty W^{[1]} will have shape (4, 2)
    oxedsymbol{igsquare}{igsquare} b^{[1]} will have shape (2, 1)
    lefta W^{[2]} will have shape (1, 4)
    lacksquare b^{[2]} will have shape (1, 1)
 10. In the same network as the previous question, what are the dimensions of Z^{[1]} and A^{[1]}?
                                                                                                                          1 point
    igcirc Z^{[1]} and A^{[1]} are (1,4)
    igcirc Z^{[1]} and A^{[1]} are (4,1)
     igotimes Z^{[1]} and A^{[1]} are (4,m)
```

igcirc $Z^{[1]}$ and $A^{[1]}$ are (4,2)
